

What is a Computer?

Computers are devices that take input, process information, store data, and produce output. They are used every day in phones, laptops, gaming systems, cars, and many other technologies.

Bohm-Jacopini

Bohm-Jacopini talks about 2 computer scientists, Corrado Böhm and Giuseppe Jacopini, who proved the **Structured Programming Theorem** in 1966. In the theorem, they showed that any computer program can be written using only three basic control structures:

1. **Sequence**-Carrying out instructions in order.
2. **Selection**-Making decisions using conditions such as if else statements.
3. **Repetition**-Repeating instructions with loops until task is completed.

The Structured Programming Theorem is important because it showed that complex programs can be built from a few simple ideas. Modern programming languages use these concepts to help developers create reliable and organized software.

3 Definitions of a Computer:

- A programmable electronic device that can store, retrieve, and process data.
- A device that accepts data, performs processing operations on that data, and supplies the results of these operations.
- An electrical device operating under the control of instructions stored in its own memory that can accept data, process it, produce information, and store it for future use.
